Li[P₃C₂Bu₂] reage com BrCH(SiMe₃)₂, via adição oxidativa, formando um novo composto organofosforado de fórmula molecular P₆C₄Bu₄CHSiMe₃ (1). O composto 1 foi caracterizado espectroscopicamente e sua estrutura molecular determinada através de difração de raios X de monocristais. Juntamente com 1, foi caracterizado outro composto (2) com a mesma fórmula molecular, mas apresentando uma estrutura completamente saturada.

Reaction of Li(P₃C₂Bu₂) with BrCH(SiMe₃)₂ results in a novel organophosphorus compound with the formula, P₆C₄Bu₄CHSiMe₃ (1). Compound 1 was fully characterised spectroscopically and its unique molecular structure determined by single crystal X-ray diffraction. Another isomer (2) with a saturated structure was also fully characterised.

Keywords: organophosphorus compounds, multinuclear NMR, X-ray molecular structure

Introduction

The chemistry of organophosphorus compounds is in constant development,¹ and it was the synthesis of P≡C₅Bu in 1981,² the first stable phosphaalkyne at room temperature, that marked the beginning of this fascinating field of chemistry. This terbutylphosphaalkyne can undergo cyclo oligomerisation reactions to produce rings and cages. There are reports in the literature of compounds containing from 2 to 6 P≡C₅Bu units with structures similar to those of the hydrocarbon analogues.³ The anionic rings (P₃C₂Bu₂)⁺ (3) and (P₃C₃Bu₃)⁺ (4) have also been used as starting materials for the syntheses of several cages compounds containing phosphorus, e.g. P₅C₅Bu₅, P₄C₄Bu₄H₂, usually by oxidative coupling reactions using metal complexes³ and protonating reagents.⁴

Using phosphaalkyne, P≡C₅Bu, and an iron complex, [Fe(η⁶-C₆H₆)(η⁴-C₁₀H₈)], Zenneck and co-workers⁵ have prepared several organophosphorus compounds including P₅C₅Bu₅CHBu (5) which contains two P₃C₂Bu₂ rings bonded together, and a CHBu group bridging two phosphorus atoms. Very recently, Avent et al.⁶ reported the synthesis of P₆C₄Bu₄GeI₂ (6), whose structure is similar to that of compound 5 but with a GeI₂ fragment at the bridging position.
Results and Discussion

We report herein another oxidative coupling reaction involving the anionic ring 3 to give a new unsaturated structure of formula \( \text{P}_6\text{C}_4\text{Bu}^\text{t}_4\text{CHSiMe}_3 (\text{I}) \). This new cage compound has an open structure with two P=C double bonds and a CHSiMe\(_3\) group bridging two phosphorus atoms. Another isomer of this species, compound 2, was isolated from the same reaction mixture. This compound has a completely saturated structure, similar to that observed for compounds 5 and 6, but with a CHSiMe\(_3\) fragment at the bridging position, instead of CHBu\(^t\) and GeI\(_2\), respectively.

Compounds 1 and 2 were synthesised from the reaction of equimolar amounts of 3 with a bulky group 7 BrCH(SiMe\(_3\))\(_2\), in DME. The mechanism of formation of both isomers is not clear, but one can speculate that it could take place via the well known 1,2,4-triphosphole (7) \(^9\) which is also identified in the reaction mixture and probably dimerises to give 1 and 2 with loss of CH(SiMe\(_3\))\(_3\), which was not isolated. Compound 2 was also prepared in low yield (6.4\%) by Nixon and co-workers \(^{10}\) using a cobalt complex to promote the coupling.

Compounds 1 and 2, both air and moisture stable, were characterised by mass spectrometry, \(^1\)H, \(^{13}\)C and \(^{31}\)P NMR spectroscopy and had their structures determined by single crystal X-ray diffraction studies.

The mass spectrum of 1 exhibits a molecular ion peak at \( m/z \) 548, and the \(^{31}\)P{\(^1\)H} NMR spectrum shows six resonances, two typical of \( sp^2 \) hybridised phosphorus with their chemical shifts in the high frequency region (\( \delta \) 346.7 and 294.7) and only small couplings indicating that no direct P-P bonds are present. \(^{11}\) The remaining resonances are all typical of \( sp^3 \) phosphorus (\( \delta \) 74.6, 45.6, 30.0 and -18.1). The resonance at \( \delta \) 75.0 shows two large coupling constants \( (J_{P1/P2}) 268.2 \) and \( J_{P4/P5} 317.5 \) Hz) giving evidence that this phosphorus atom is bonded to other two in a P-P-P network.

The new tetracyclic structure of 1, presented in Figure 1, was elucidated by single crystal X-ray analysis \(^{12}\) and reveals three phosphorus atoms bonded together, P(2)-P(1)-P(5), and two P=C double bonds. The distance between P(2)-P(1) and P(1)-P(5) (2.250(1) and 2.191(2) Å, respectively) are in the expected range for a P-P single bond. \(^{13}\) The two double bonds P(3)-C(3) and P(4)-C(5) (1.668(4) and 1.676(4) Å, respectively) are the shortest ones in this cage framework and lie in the expected range previously reported (1.64 - 1.69 Å). \(^{14}\) The C(3) and C(5) carbons show bond angles typical of \( sp^3 \)-hybridised atoms.

Isomer 2 with the same MS molecular ion \( m/z \) 548 was characterised by \(^{31}\)P{\(^1\)H} NMR spectroscopy showing six resonances all typical of \( sp^3 \) hybridised phosphorus. The two resonances at \( \delta \) 196.9 and 178.4 with small P-P couplings (in the 15-30 Hz range) indicate the presence of two phosphorus bonded only to carbon atoms. \(^{15}\) Large P-P couplings for the remaining four resonances \( (J_{P1/P2}) 228.4 \) and \( J_{P4/P5} 237.2 \) Hz) suggest four phosphorus atoms bonded together two by two.

The molecular structure of 2 is shown in Figure 2. \(^{16}\) It presents the two five membered rings joined side by side.

![Scheme 1](image-url)
by a CHSiMe₃ bridge forming a cage with four five-membered and three four-membered rings. The average C-C and P-C distances are 1.54(2) and 1.88(1) Å, respectively, which are in the expected range.¹³,¹⁴ The P(2)-P(1) and P(4)-

P(5) bond distances are 2.201(1) and 2.190(1) Å, respectively, in agreement with the triad, P-P-P, found in structure 1.

**Acknowledgements**

This work has been supported by Brazilian agencies CNPq, FAPEMIG and FAPESP (Projeto Temático No. 98/12151-1). J.E. and A.C.D. thank FAPESP and CNPq, respectively, for the postdoctoral fellowship. We also thank Prof. J. F. Nixon (UK) for his constant encouragement.

**Supplementary Material**

Crystallographic data (excluding structure factors) for the structures in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC 173911 and 173912. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax:+44 1223 336033 or e-mail: deposit@ccdc.cam.ac.uk).

8. General procedure for the preparation of P₃Bu₃CHSiMe₃ (1) and 2: HCBn(SiMe₃)₂ (0.6 mL, 2.31 mmol) in DME (10 mL), was added slowly to a solution of Li[P(C₃Bu)₂] (2.31 mmol) in 15 mL of DME, at -30 °C and the resulting mixture was stirred for 20 h. The LiBr formed during the reaction was filtered off and the solvent evaporated under vacuum. The residue was purified by column chromatography (kieselgel/hexane) to give two yellow bands. The first was characterised as compound 1 (250 mg, 20%), and the second as compound 2 (200 mg, 16%). Recrystallisation from hexane to room temperature afforded yellow crystals suitable for X-ray diffraction study for both compounds.
